Abstract. In the manufacturing industry, many product characteristics are of one-sided tolerances. The process capability indices $C_p^u(u, v)$ and $C_p^l(u, v)$ can be used to measure process performance. Most research work related to capability indices assumes no gauge measurement errors. This assumption insufficiently reflects real situations even when advanced measuring instruments are used. In this paper we show that using a critical value without taking into account these errors, severely underestimates the α -risk which causes a less accurate testing capacity. In order to improve the results we suggest the use of an adjusted critical value, and we give a Maple program to get it. An example in a polymer granulates manufactory is presented to illustrate this approach.

Keywords: Process capability indices; gauge measurement error; one-sided tolerance process; critical value; power test

1 Introduction

A common way to summarize the process performance is by using the process capability indices which provide information with respect to engineering specification. The two capability indices which have been widely used in manufacturing industry are C_p and C_{pk} . The C_p index measures only the potential of a process to produce acceptable product, and does not take into account where the process is centred. C_{pk} index is computed using both location and dispersion information about the process. However, the indices C_p and C_{pk} consider only the process mean and standard deviation, but not the proximity of the process mean to the target value of the process characteristic. Chan et al. [1] proposed the C_{pm} index to consider the proximity of the process mean to the target value. The C_{pmk} index suggested by Pearn et al. [2] is a combination of C_{pk} and C_{pm} , so it has the advantages of both C_{pk} and C_{pm} . For a process with lower and upper tolerance limits LSL and USL , and a target T set to the midpoint $m = (LSL + USL)/2$ of the tolerance interval, Vännman [3] constructed a unified superstructure for the four previous basic indices which can be defined as

$$C_p(u, v) = \frac{d - u|\mu - m|}{3\sqrt{\sigma^2 + v(\mu - T)^2}},$$

where $d = (USL - LSL)/2$ is the half-length of the tolerance interval, μ is the mean, σ is the standard deviation, and u and v are two non-negative parameters. Although

cases with symmetric tolerances ($T = m$) are common in practical situations, cases with asymmetric tolerances ($T \neq m$) often occur in manufacturing industry. In general asymmetric tolerances reflect that deviations from the target are less tolerable in one direction than in the other. In this situation Chen and Pearn [4] suggested to use the family

$$C_p''(u, v) = \frac{d^* - uA^*}{3\sqrt{\sigma^2 + vA^2}},$$

where $A = \max\{d(\mu - T)/D_u, d(T - \mu)/D_l\}$, $A^* = \max\{d^*(\mu - T)/D_u, d^*(T - \mu)/D_l\}$, $D_u = USL - T$, $D_l = T - LSL$, and $d^* = \min\{D_u, D_l\}$. Grau [5] suggests choosing parameters u and v according to the importance the user attaches to the process centring and/or to the percentage of non-conforming, which are the most important criteria to measure the process performance.

This paper considers the situation where a shift of the mean from the target in one direction appears less serious to the user, so that he is induced to define only one tolerance. Grau [6] suggests to the user to quantify the risk he considers the least serious when the mean shifts in the opposite direction from the target. When the risk is considered as k times less serious, Grau [6] suggests using the families

$$C_p^u(u, v) = \frac{D_u - uA_u^*}{3\sqrt{\sigma^2 + vA_u^{*2}}}, \text{ and } C_p^l(u, v) = \frac{D_l - uA_l^*}{3\sqrt{\sigma^2 + vA_l^{*2}}}, \quad (1)$$

for an upper and a lower tolerance, where $A_u^* = \max(\mu - T, (T - \mu)/k)$, and $A_l^* = \max((\mu - T)/k, T - \mu)$. Note that the letter u used in superscript is an abbreviation of "upper", and so too is independent of the first of the

* Correspondence: daniel.grau@univ-pau.fr

two parameters (u, v) of the indices family. The choice of the constant $k (\geq 1)$ is approximate, thus $C_p^u(u, v)$ and $C_p^l(u, v)$ have been constructed so that they are independent of k when the mean shifts toward the tolerance limit. Note that the choice $k = 1$ comes to take into account similar risks on the right and on the left. If for instance the risk on the left is considered as nil, taking k infinite is sufficient. In this case when $\mu < T$, $C_p^u(u, v) = D_u/(3\sigma)$, which is independent of μ , and which is nothing but the potential capability C_p . For $C_p^u(u, v)$ and $C_p^l(u, v)$ Grau [7] suggests choosing parameters u and v according to the importance the user attaches to the process centring and/or to the percentage of non-conforming.

The capability indices calculated from data obtained from samples of manufactured items are not the true values but only estimations. Therefore, a certain amount of uncertainty, due to the sampling error, is necessarily present in the evaluation of the process performance, and in order to avoid erroneous interpretations, it is important to know the statistical properties of the estimators. A further source of uncertainty is given by the measurements errors. Mittag [8] was the first author to link capability indices and measurement errors. For the $C_p, C_{pk}, C_{PU}, C_{PL}, C_{pm}, C_{pmk}$ and $C_p''(u, v)$ indices, Pearn and Liao [9–11], Pearn et al. [12], Hsu et al. [13], Grau [14, 15] establish reliable lower confidence bounds and reliable critical values to estimate and test the process capability with gauge measurements errors.

In this paper, we consider the one-sided process capability indices $C_p^u(u, v)$ and $C_p^l(u, v)$, and construct a critical value to test whether a process is capable when gauge measurement errors are present.

This article is organized as follows. In Section 2, for one-sided tolerance process we quickly report the main results concerning the effects of gauge measurement errors on theoretical capability indices $C_p^u(u, v)$ and $C_p^l(u, v)$. In Section 3 we give the sampling distribution of capability indices in the presence of measurements errors. Sections 4 and 5 give critical values and adjusted critical values to test process capability when gauge measurement errors are noticed. Finally, a real example is presented in the last section.

2 The indices $C_p^u(u, v), C_p^l(u, v)$, and the gauge measurement errors

Suppose that the gauge measurement errors can be described as a random variable $M \sim N(0, \sigma_M^2)$. Mittag [8] define the degree of error contamination as

$$\tau = \frac{\sigma_M}{\sigma}.$$

Suppose that $X \sim N(\mu, \sigma^2)$ represents the relevant quality characteristic of the manufacturing process. In practice the observed variable G (with gauge measurement errors) is measured rather than the true variable X . It is further assumed that X and M are additively linked according to $G = X + M$ and that X and M are stochastically

independent. Then we have $G \sim N(\mu, \sigma_G^2 = \sigma^2 + \sigma_M^2)$ and the empirical process capability indices $C_p^{uG}(u, v)$ and $C_p^{lG}(u, v)$ are obtained by formula (1) after substituting σ_G for σ .

$$\begin{aligned} C_p^{uG}(u, v) &= \frac{D_u - uA_u^*}{3\sqrt{\sigma_G^2 + vA_u^{*2}}}, \\ C_p^{lG}(u, v) &= \frac{D_l - uA_l^*}{3\sqrt{\sigma_G^2 + vA_l^{*2}}}. \end{aligned} \tag{2}$$

Obviously if $\sigma_M = 0$, then the empirical process capability, $C_p^{uG}(u, v)$ and $C_p^{lG}(u, v)$, reduce to the basic indices, $C_p^u(u, v)$ and $C_p^l(u, v)$. Since the variation of the observed data is greater than the variation of the original data, the denominator of the indices $C_p^{uG}(u, v)$ and $C_p^{lG}(u, v)$ becomes larger and we would understate the true capability of the process if the empirical data are used. The relation between $C_p^u(u, v), C_p^l(u, v)$, the true process capability, and $C_p^{uG}(u, v), C_p^{lG}(u, v)$, the empirical process capability, can be expressed as

$$\begin{aligned} C_p^{uG}(u, v) &= \frac{\sqrt{1 + v\xi^{u2}}}{\sqrt{1 + \tau^2 + v\xi^{u2}}} C_p^u(u, v), \\ C_p^{lG}(u, v) &= \frac{\sqrt{1 + v\xi^{l2}}}{\sqrt{1 + \tau^2 + v\xi^{l2}}} C_p^l(u, v) \end{aligned} \tag{3}$$

where $\xi^u = \max(\xi, -\xi/k)$, $\xi^l = \max(\xi/k, -\xi)$ and $\xi = (\mu - T)/\sigma$. It is clear that the ratio $C_p^{uG}(u, v)/C_p^u(u, v)$ is decreasing function of τ . Then the measurements errors understate the true theoretical capability of the process. However, the theoretical capability is unknown and is estimated from sample data. Thus, in the following sections we deal with the effects of measurement errors on the behavior of estimated capability indices.

3 Sampling distribution of $\hat{C}_p^{uG}(u, v)$ and $\hat{C}_p^{lG}(u, v)$

Subsequently we will only develop the case of an upper tolerance and without difficulty will deduce the similar results in the case of a lower tolerance.

Let X_1, X_2, \dots, X_n be a random sample from a normal distribution with mean μ and variance σ^2 measuring the characteristic of the process. To estimate the $C_p^u(u, v)$ and $C_p^l(u, v)$ indices, we replace μ and σ^2 by their conventional estimators $\bar{X} = (\sum_{i=1}^n X_i)/n$, and $S^2 = \sum_{i=1}^n (X_i - \bar{X})^2/n$. Thus we define the estimators $\hat{C}_p^u(u, v)$ and $\hat{C}_p^l(u, v)$ as

$$\begin{aligned} \hat{C}_p^u(u, v) &= \frac{D_u - u\hat{A}_u^*}{3\sqrt{S^2 + v\hat{A}_u^{*2}}}, \\ \hat{C}_p^l(u, v) &= \frac{D_l - u\hat{A}_l^*}{3\sqrt{S^2 + v\hat{A}_l^{*2}}}, \end{aligned}$$

$$\xi^u = \frac{-C_p^u u/3 + \sqrt{(C_p^u)^2 (u/3)^2 + ((C_p^u)^2 - c^2)(vc^2 - (u/3)^2)}}{vc^2 - (u/3)^2}.$$

where $\hat{A}_u^* = \max(\bar{X} - T, (T - \bar{X})/k)$ and $\hat{A}_l^* = \max((\bar{X} - T)/k, T - \bar{X})$.

Under the assumption of normality, and for $(u, v) \neq (0, 0)$, Grau [7] gives the cumulative distribution function of $\hat{C}_p^u(u, v)$ which can be rewritten as

$$F_{\hat{C}_p^u(u, v)}(x) = 1 - \int_0^{K(x)} H(x, t) dt, \text{ for } x > 0, \quad (4)$$

where $K(x) = B_u \sqrt{n}/(u + 3x\sqrt{v})$, $B_u = D_u/\sigma = 3C_p^u$ with $C_p^u = C_p^u(0, 0)$,

$H(x, t) = F_K((\frac{B_u \sqrt{n} - ut}{3x})^2 - vt^2) f_{Z_u}(t)$, with $F_K(x)$ is the cumulative χ_{n-1}^2 distribution, $f_{Z_u}(t) = \phi(t - \sqrt{n}\xi) + k\phi(kt + \sqrt{n}\xi)$ and $\phi(x)$ is the probability density of the standard normal distribution $N(0, 1)$.

For $C_p^l(u, v)$, we obtain similar results replacing B_u by $B_l = D_l/\sigma = 3C_p^l$ with $C_p^l = C_p^l(0, 0)$, and $f_{Z_u}(t)$ by $f_{Z_l}(t) = k\phi(kt - \sqrt{n}\xi) + \phi(t + \sqrt{n}\xi)$.

When there are gauge measurement errors, the variable G is measured rather than the true variable X . (G_1, G_2, \dots, G_n) are selected randomly from a stable process following a normal distribution $N(\mu, \sigma_G^2)$. We denote, $\bar{G} = \sum_{i=1}^n G_i/n$, $S_G^2 = \sum_{i=1}^n (G_i - \bar{G})^2/n$, $\xi_G^u = \max(\xi_G, -\xi_G/k)$, $\xi_G^l = \max(\xi_G/k, -\xi_G)$ and $\xi_G = (\mu - T)/\sigma_G$, and consider the following natural estimators $\hat{C}_p^{uG}(u, v)$ and $\hat{C}_p^{lG}(u, v)$ defined as

$$\hat{C}_p^{uG}(u, v) = \frac{D_u - u\hat{A}_u^{*G}}{3\sqrt{S_G^2 + v\hat{A}_u^{*G^2}}},$$

$$\hat{C}_p^{lG}(u, v) = \frac{D_l - u\hat{A}_l^{*G}}{3\sqrt{S_G^2 + v\hat{A}_l^{*G^2}}},$$

where $\hat{A}_u^{*G} = \max(\bar{G} - T, (T - \bar{G})/k)$ and $\hat{A}_l^{*G} = \max((\bar{G} - T)/k, T - \bar{G})$.

Thus for $(u, v) \neq (0, 0)$, the cumulative distribution of $\hat{C}_p^{uG}(u, v)$ is

$$F_{\hat{C}_p^{uG}(u, v)}(x) = 1 - \int_0^{K_G(x)} H_G(x, t) dt, \text{ for } x > 0, \quad (5)$$

where $K_G(x) = B_u^G \sqrt{n}/(u + 3x\sqrt{v})$, $B_u^G = D_u/\sigma_G = 3C_p^{uG}$ with $C_p^{uG} = C_p^{uG}(0, 0)$,

$$H_G(x, t) = F_K\left(\left(\frac{B_u^G \sqrt{n} - ut}{3x}\right)^2 - vt^2\right) f_{Z_u^G}(t),$$

with $f_{Z_u^G}(t) = \phi(t - \sqrt{n}\xi_G) + k\phi(kt + \sqrt{n}\xi_G)$.

For $\hat{C}_p^{lG}(u, v)$, we obtain similar results replacing B_u^G by $B_l^G = D_l/\sigma_G = 3C_p^{lG}$ with $C_p^{lG} = C_p^{lG}(0, 0)$, and $f_{Z_u^G}(t)$ by $f_{Z_l^G}(t) = k\phi(kt - \sqrt{n}\xi_G) + \phi(t + \sqrt{n}\xi_G)$.

4 Capability testing based on $\hat{C}_p^{uG}(u, v)$ or $\hat{C}_p^{lG}(u, v)$

To determine whether a given process meets the preset capability requirement, we could consider the following statistical hypotheses testing:

- $H_0 : C_p^u(u, v) \leq c$ Process is not capable;
- $H_1 : C_p^u(u, v) > c$ Process is capable;

where c is the required process capability. If the calculated process capability $\hat{C}_p^u(u, v)$ is greater than the critical value c_0 , we reject the null hypothesis and conclude that the process is capable with error α , which is the chance of incorrectly concluding an incapable process as capable. Given values of c and α , from (4) the critical value c_0 can be determined by solving the equation $\alpha = P(\hat{C}_p^u(u, v) > c_0 | C_p^u(u, v) = c) = \int_0^{K(c_0)} H(c_0, t) dt$, where from (A.9) in Appendix A, $B_u = 3C_p^u = 3\sqrt{1 + v\xi^{u^2}}c + u\xi^u$. However, since the process parameters μ and σ are unknown, parameters ξ and therefore ξ^u are unknown. We replace ξ and ξ^u by the observation of the natural estimators $\hat{\xi} = (\bar{X} - T)/S$ and $\hat{\xi}^u = \max(\hat{\xi}, -\hat{\xi}/k)$. Note that we use the same symbols $\hat{\xi}$ and $\hat{\xi}^u$ for the estimators as well as the estimations.

In the presence of measurements errors, $C_p^{uG}(u, v)$ is measured rather than the true variable $C_p^u(u, v)$. Thus the α -risk denoted by α_G is defined as $\alpha_G = P(\hat{C}_p^{uG}(u, v) > c_0 | C_p^u(u, v) = c)$. Earlier discussions indicate that we underestimate the real process capability using $\hat{C}_p^{uG}(u, v)$ instead of $\hat{C}_p^u(u, v)$. The probability of $\hat{C}_p^{uG}(u, v)$ being greater than c_0 will be less important than by using $\hat{C}_p^u(u, v)$. Thus α_G , the α -risk using $\hat{C}_p^{uG}(u, v)$ to estimate $C_p^u(u, v)$ is less than α , using $\hat{C}_p^u(u, v)$ when estimating $C_p^u(u, v)$. To illustrate the performance of α_G versus τ , we have considered the particular case $u = 0.5$, $v = 1.5$, $k = 3$, $c = 1$ and 1.5 , $\alpha = 0.05$, and have plotted curves α_G for various C_p^u values. The critical value c_0 is obtained from (4) where ξ is defined from (A.2) and ξ^u is defined from (A.14) as

see equation above.

Then from (5) we compute $\alpha_G = \int_0^{K_G(c_0)} H_G(c_0, t) dt$, where C_p^{uG} and ξ_G are obtained from (A.12) and (A.5). Figure 1 plots α_G versus $\tau \in [0, 1]$ with $n = 30, 50, 70, 100, 150$ for $C_p^u = c(0.5)(c + 1)$. Note that for $\tau = 0$, $\alpha_G = \alpha$. In Figure 1, α_G decreases as τ or n increases, and the decreasing rate is more significant with large c and small C_p^u .

We now consider the power of the test, the chance of correctly concluding a capable process as capable. It can

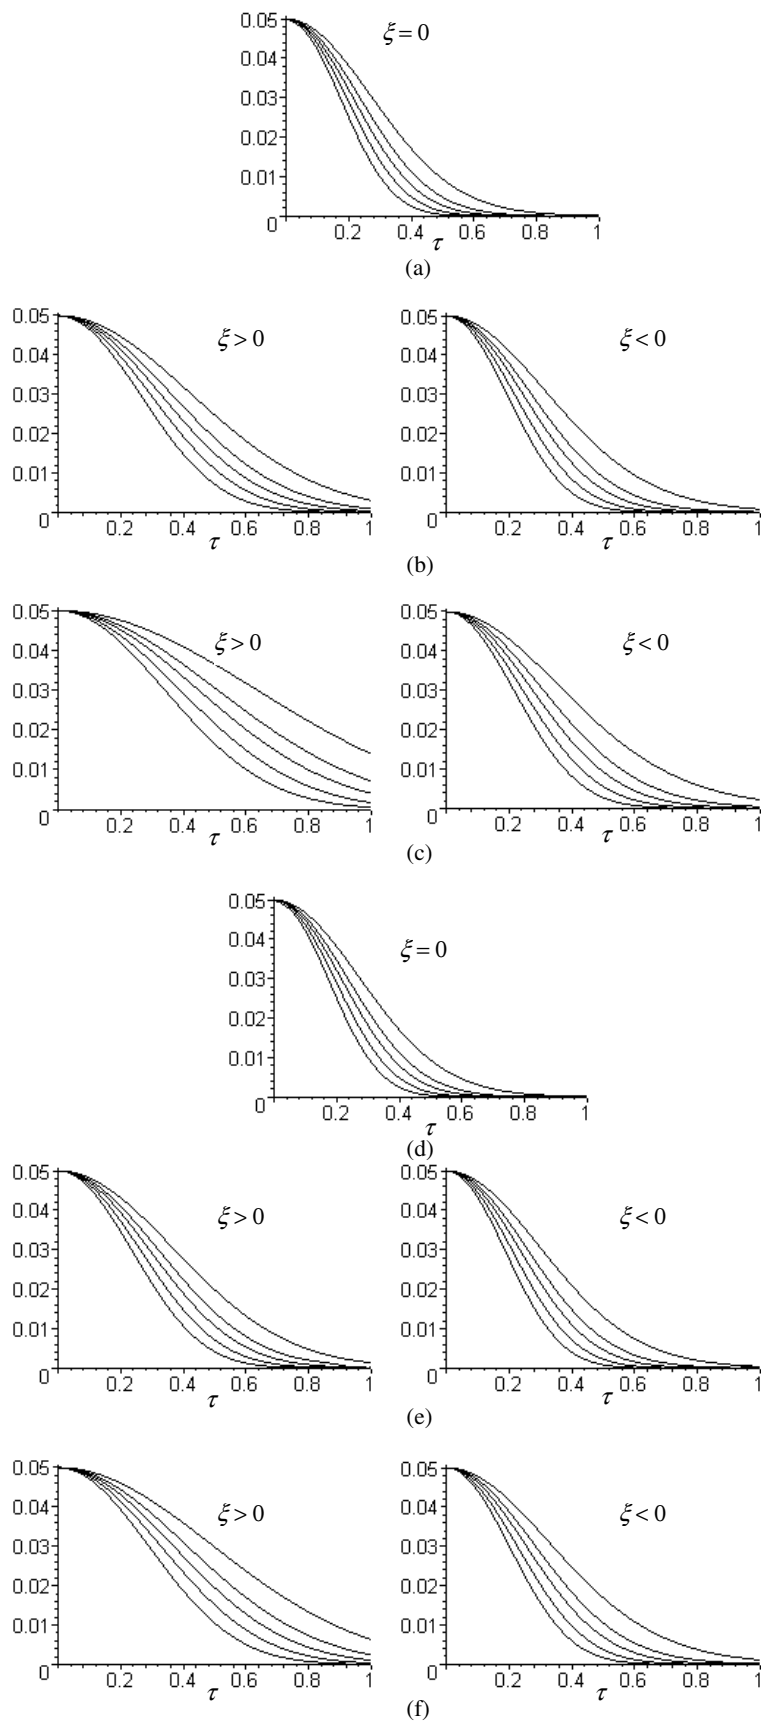

Fig. 1. Plots of α_G versus τ with $n = 30, 50, 70, 100, 150$ (top to bottom), $u = 0.5, v = 1.5, k = 3, \alpha = 0.05$ for (a) $c = 1, C_p^u = 1$; (b) $c = 1, C_p^u = 1.5$; (c) $c = 1, C_p^u = 2$, (d) $c = 1.5, C_p^u = 1.5$; (e) $c = 1.5, C_p^u = 2$; (f) $c = 1.5, C_p^u = 2.5$.

be computed as $\pi(C_p^u(u, v)) = P(\hat{C}_p^u(u, v) > c_0 | C_p^u(u, v)) = \int_0^{K(c_0)} H(c_0, t) dt$, with from (A.9) $B_u = 3C_p^u = 3\sqrt{1 + v\xi^{u^2}c + u\xi^u}$.

In the presence of measurements errors, the power of the test denoted by π_G is as follows $\pi_G(C_p^u(u, v)) = P(\hat{C}_p^{uG}(u, v) > c_0 | C_p^u(u, v)) = \int_0^{K_G(c_0)} H_G(c_0, t) dt$. To illustrate the performance of π_G versus τ , we consider the particular case $u = 0.5$, $v = 1.5$, $k = 3$ and plot the curves π_G for various C_p^u et $C_p^u(u, v)$ values. In the previous equation, C_p^{uG} , ξ^u , ξ and ξ_G are obtained from (A.12), (A.14), (A.2) and (A.5). Figure 2 plots π_G versus $\tau \in [0, 1]$ with $n = 50$, $\alpha = 0.05$, $c = 1.00$ and 1.50 , $C_p^u(u, v) = c(0.20)(c + 1)$, and $C_p^u = C_p^u(u, v)$, $C_p^u(u, v) + 0.33$ and $C_p^u(u, v) + 0.5$. In Figure 2, we see that π_G decreases as τ increases and the decreasing rate is more significant with large c . The presence of measurements errors can have a very substantial effect on π_G . For instance, for $c = 1.5$ and $C_p^u = C_p^u(u, v) = 2.3$ (Fig. 2d), π_G is approximately equal to 1 without measurement errors. However, when $\tau = 1$, π_G is approximately equal to 0.15 for $\xi > 0$ and approximately equal to 0.41 for $\xi < 0$.

5 Adjusted critical values

As we have seen in the previous section, the α -risk and the test power decrease with measurement errors. The capability testing results would be misleading if the producers do not take account of the gauge measurements errors. Thus, in order to improve the test power, we revise the critical value, denoted by c_0^A , to satisfy $c_0^A < c_0$. Let $\alpha_A = P(\hat{C}_p^{uG}(u, v) > c_0^A | C_p^u(u, v) = c)$ and $\pi_A(C_p^u(u, v)) = P(\hat{C}_p^{uG}(u, v) > c_0^A | C_p^u(u, v))$, be the α -risk and the test power using the adjusted critical value. Since $c_0^A < c_0$, $P(\hat{C}_p^{uG}(u, v) > c_0^A)$ is greater than $P(\hat{C}_p^{uG}(u, v) > c_0)$, and both π_A and α_A increase. To ensure that the α -risk is within the pre-set magnitude, we set $\alpha_A = \alpha$, and solve equation $\alpha = P(\hat{C}_p^{uG}(u, v) > c_0^A | C_p^u(u, v) = c)$ to obtain c_0^A . Thus from (5), we must solve

$$\alpha = \int_0^{K_G(c_0^A)} H_G(c_0^A, t) dt. \quad (6)$$

Since the process parameters μ and σ_G are unknown, then ξ_G is also unknown. Thus the previous equation involves the unknown parameters ξ_G and C_p^{uG} or C_p^u from (A.12). We replace ξ_G by the observed value $\hat{\xi}_G$, and from (A.13) C_p^u can be obtained by

$$C_p^u = \sqrt{1 + \tau^2} \left(\frac{\sqrt{1 + v\hat{\xi}_G^2} \sqrt{1 + v\hat{\xi}^{u^2}}}{\sqrt{1 + \tau^2 + v\hat{\xi}^{u^2}}} c + u\hat{\xi}_G^u/3 \right), \quad (7)$$

where $\hat{\xi}_G^u$ and $\hat{\xi}^u$ are defined from (A.3) and (A.7) as follows

$$\hat{\xi}_G^u = \max\left(\hat{\xi}_G, -\hat{\xi}_G/k\right),$$

$$\text{and } \hat{\xi}^u = \max\left(\hat{\xi}_G\sqrt{1 + \tau^2}, -\hat{\xi}_G\sqrt{1 + \tau^2}/k\right).$$

With that adjusted critical value c_0^A , we can calculate the test power noted down as π_A . Let C_{p1}^u be the value of C_p^u the solution of equation (7). The test power can be calculated as follows

$$\pi_A(C_p^u(u, v)) = P\left(\hat{C}_p^{uG}(u, v) > c_0^A | C_p^u(u, v), C_p^u = C_{p1}^u\right)$$

$$= \int_0^{K_1(c_0^A)} H_1(c_0^A, t) dt,$$

with

$$K_1(x) = B_{u1}^G \sqrt{n} / (u + 3x\sqrt{v}),$$

$$B_{u1}^G = 3C_{p1}^{uG} = \frac{3C_{p1}^u}{\sqrt{1 + \tau^2}} \text{ from (A.12),}$$

$$H_1(x, t) = F_K \left(\left(\frac{B_{u1}^G \sqrt{n} - ut}{3x} \right)^2 - vt^2 \right) f_{Z_{u1}^G}(t),$$

$$f_{Z_{u1}^G}(t) = \phi(t - \sqrt{n}\xi_{G1}) + k\phi(kt + \sqrt{n}\xi_{G1}),$$

$$\xi_{G1} = \begin{cases} \xi_{G1}^u & \text{if } \xi_{G1} > 0 \\ -k\xi_{G1}^u & \text{if } \xi_{G1} < 0 \end{cases} \text{ from (A.4),}$$

$$\xi_{G1}^u = \xi_1^u / \sqrt{1 + \tau^2} \text{ from (A.8),}$$

and ξ_1^u is obtained substituting C_{p1}^u to C_p^u in (A.14). ξ_{G1} and ξ_G have the same sign, but ξ_G is unknown. Thus we replace ξ_G by the observed value $\hat{\xi}_G$, and replace ξ_{G1} by $\hat{\xi}_{G1}$ defined by $\hat{\xi}_{G1} = \begin{cases} \xi_{G1}^u & \text{if } \hat{\xi}_G > 0 \\ -k\xi_{G1}^u & \text{if } \hat{\xi}_G < 0 \end{cases}$.

For a process with a lower tolerance, we obtain similar results replacing C_{p1}^u by C_{p1}^l the solution of equation

$$C_{p1}^l = \sqrt{1 + \tau^2} \left(\frac{\sqrt{1 + v\hat{\xi}_G^{l2}} \sqrt{1 + v\hat{\xi}^{l2}}}{\sqrt{1 + \tau^2 + v\hat{\xi}^{l2}}} c + u\hat{\xi}_G^l/3 \right), \quad (8)$$

$\hat{\xi}_G^u$ by $\hat{\xi}_G^l = \max(\hat{\xi}_G/k, -\hat{\xi}_G)$, $\hat{\xi}^u$ by $\hat{\xi}^l = \max(\hat{\xi}_G\sqrt{1 + \tau^2}/k, -\hat{\xi}_G\sqrt{1 + \tau^2})$, B_{u1}^G by $B_{u1}^G = 3C_{p1}^l/\sqrt{1 + \tau^2}$, $f_{Z_{u1}^G}(t) = \phi(t - \sqrt{n}\hat{\xi}_{G1}) + k\phi(kt + \sqrt{n}\hat{\xi}_{G1})$ by $f_{Z_{u1}^G}(t) = k\phi(kt - \sqrt{n}\hat{\xi}_{G1}) + \phi(t + \sqrt{n}\hat{\xi}_{G1})$, where $\hat{\xi}_{G1} = \begin{cases} k\xi_{G1}^l & \text{if } \hat{\xi}_G > 0 \\ -\xi_{G1}^l & \text{if } \hat{\xi}_G < 0 \end{cases}$, $\xi_{G1}^l = \xi_1^l/\sqrt{1 + \tau^2}$, and ξ_1^l is obtained substituting C_{p1}^l to C_p^l in (A.14).

A Maple program is developed in Appendix B to compute the adjusted critical value c_0^A and plot the power test. Figure 3 plots π_A versus $\tau \in [0, 1]$ with $u = 0.5$, $v = 1.5$, $k = 3$, $n = 50$, $\alpha = 0.05$, $c = 1.00, 1.50$,

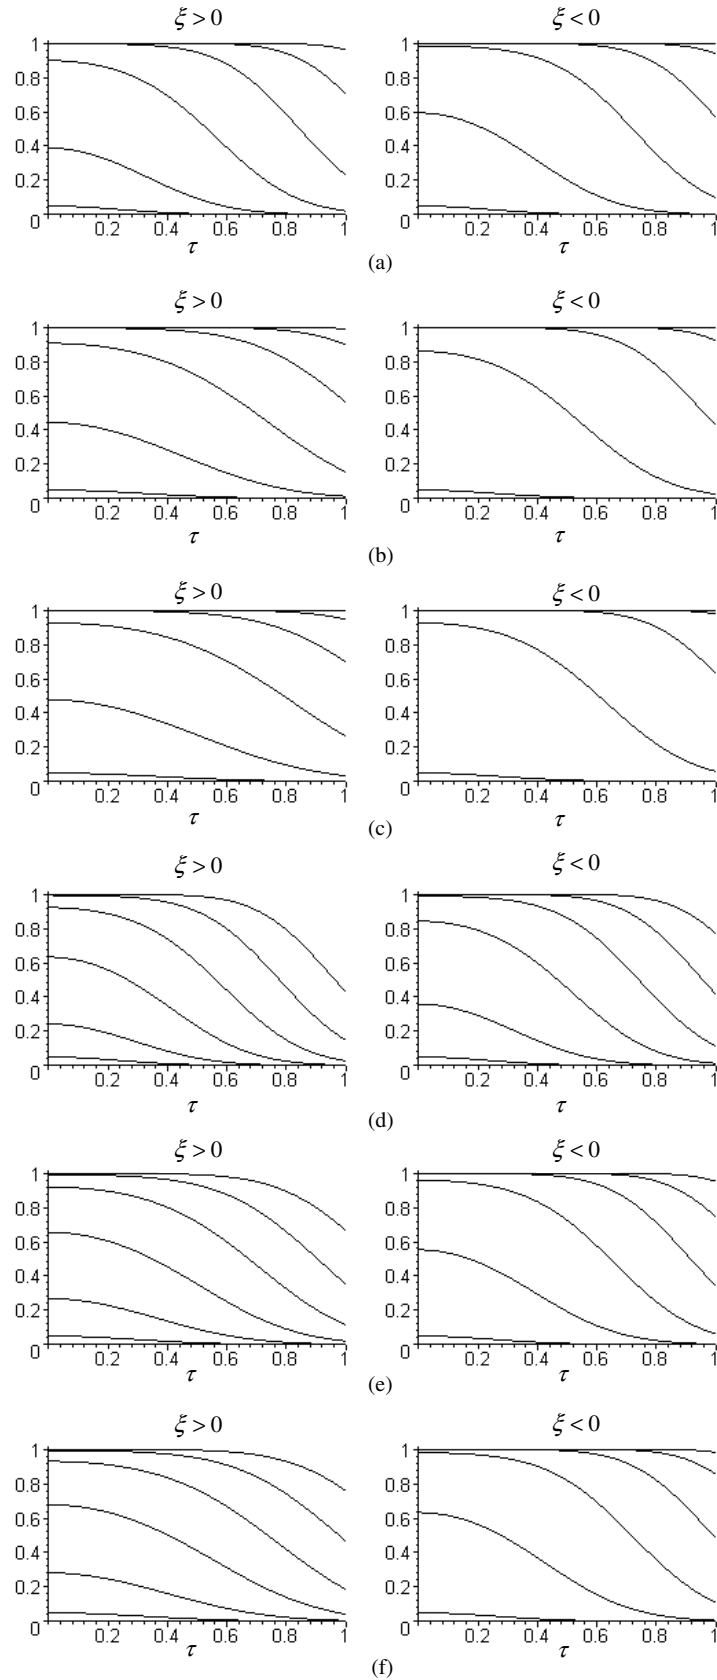

Fig. 2. Plots of π_G versus τ with $u = 0.5, v = 1.5, k = 3, n = 50, \alpha = 0.05, C_p^u(u, v) = c(0.20)(c + 1)$ (bottom to top) for (a) $c = 1$ and $C_p^u = C_p^u(u, v)$; (b) $c = 1$ and $C_p^u = C_p^u(u, v) + 0.33$; (c) $c = 1$ and $C_p^u = C_p^u(u, v) + 0.5$; (d) $c = 1.5$ and $C_p^u = C_p^u(u, v)$; (e) $c = 1.5$ and $C_p^u = C_p^u(u, v) + 0.33$; (f) $c = 1.5$ and $C_p^u = C_p^u(u, v) + 0.5$.

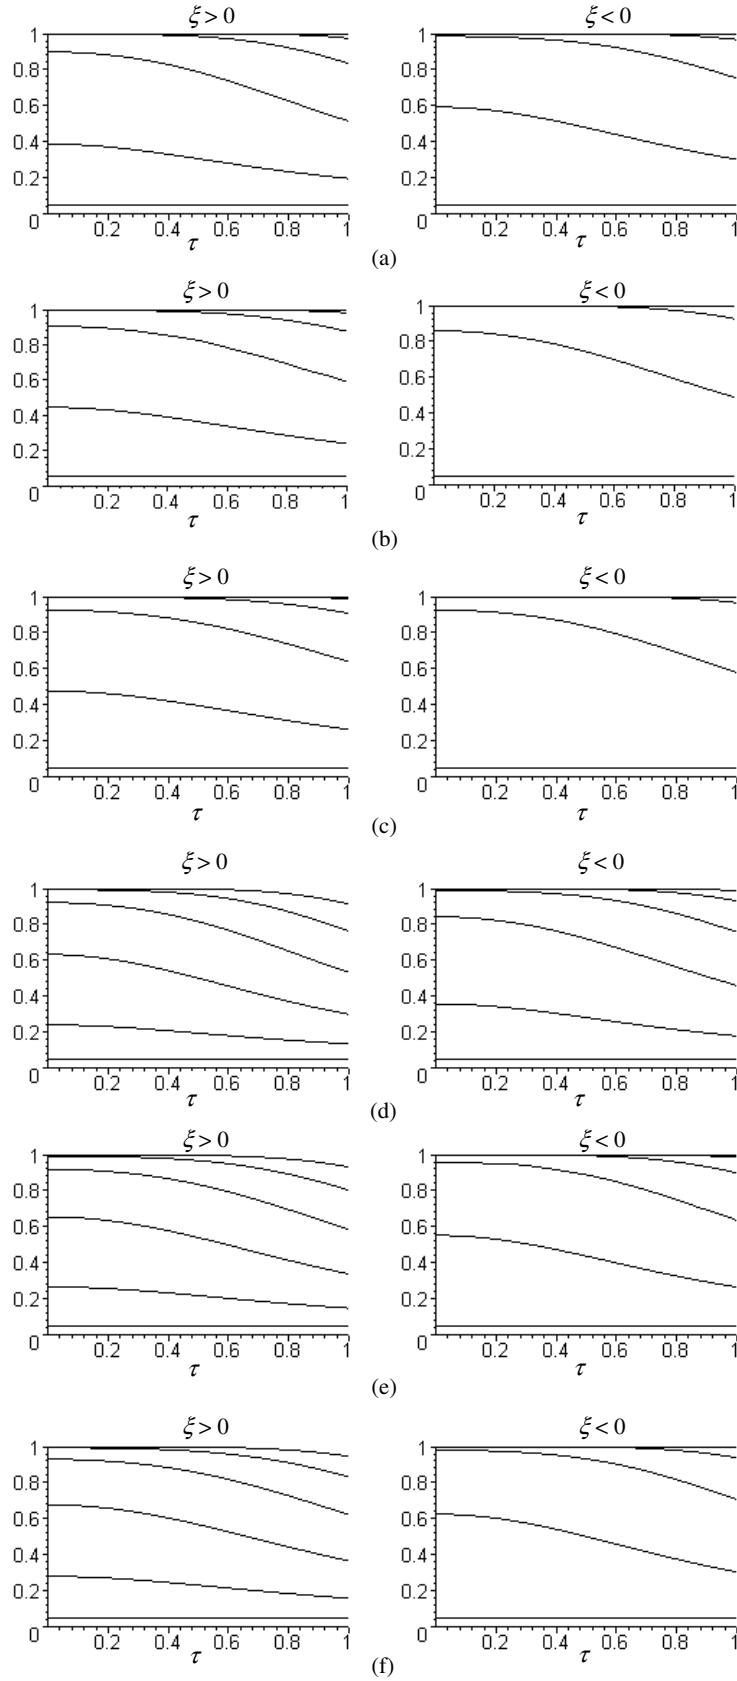

Fig. 3. Plots of π_A versus τ with $u = 0.5$, $v = 1.5$, $k = 3$, $n = 50$, $\alpha = 0.05$, $C_p^u(u, v) = c(0.20)(c + 1)$ (bottom to top) for (a) $c = 1$ and $C_p^u = C_p^u(u, v)$; (b) $c = 1$ and $C_p^u = C_p^u(u, v) + 0.33$; (c) $c = 1$ and $C_p^u = C_p^u(u, v) + 0.5$; (d) $c = 1.5$ and $C_p^u = C_p^u(u, v)$; (e) $c = 1.5$ and $C_p^u = C_p^u(u, v) + 0.33$; (f) $c = 1.5$ and $C_p^u = C_p^u(u, v) + 0.5$.

$C_p^u(u, v) = c(0.20)(c + 1)$ and $C_p^u = C_p^u(u, v)$, $C_p''(u, v) + 0.33$ and $C_p^u(u, v) + 0.5$. In Figure 3, π_A decreases as τ increases and the decreasing rate is more significant with large c . However, if we compare Figures 2 and 3, we can see that the powers corresponding to the adjusted critical values c_0^A decrease more slowly. Thus the test power is improved.

6 Example

To illustrate our approach we go back to a study carried out within the Arkema company (Grau [7]). This company manufactures different sorts of polymer granulates which are transformed for many applications such as films or bottles used for food packaging. Polymer granulates are also used as tie layer in multilayer structures, providing outstanding adhesion between several materials, or coupling agent for reinforced thermoplastics. Before polymerization, an additive, maleic anhydride, is blended. For the studied grade, the target for this additive is 1500 ppm and the necessary minimal value is 1000 ppm, i.e. the lower limit of tolerance. The cost of this additive not being very important, no upper limit has been fixed. During the manufacturing cycle, processes are considered capable when the capability indices are higher than 1.33. The objective of the Arkema company is to use a capability index with a clear interpretation in terms of centring and non-conforming. The selected index is $C_p^l(0.6, 0.2)$. So a value of $C_p^l(0.6, 0.2)$ superior or equal to 1.33 enables us to say that the process is capable as far as the percentage of manufactured non conforming items is inferior or equal to 50 ppm, and the process mean does not move away for more than 42% of the distance between the target and the lower tolerance limit (Grau [7]). We propose to determine whether the process is capable when the risk k is equal to 3, and the degree of error contamination τ is equal to 0.25. A sample of 112 values of maleic anhydride was taken to estimate the capability of the manufacturing process. Ryan-Joiner test for normality was carried out pointing out that the sample can be regarded as taken from a normal distribution process. From the sample data we have $\bar{g} = 1590.480$, $s_G = 105.914$, $\hat{\xi}_G = 0.854$, and $\hat{c}_p^{lG}(0.6, 0.2) = 1.505$, a value greater than 1.33. However this value is a specific point estimate that depends on the selected sample and does not make it possible to draw conclusions on the capability of the process. To decide whether the process is capable, that is to say if $C_p^l(0.6, 0.2) > 1.33$, we calculate the critical value using the method described in Section 5. Let the α risk be 0.05. From the Maple program in Appendix B, we obtain the critical value $c_0^A = 1.456$. Since $\hat{c}_p^{lG}(0.6, 0.2) > c_0^A$, we therefore conclude that the process is capable. We also see that if we ignore the measurements errors, the critical value may be calculated as $c_0 = 1.500$. So if another sample gives $\bar{g} = 1592.000$ and $s_G = 107.694$, we always have $\hat{\xi}_G = 0.854$, thus $c_0^A = 1.456$ and $c_0 = 1.500$. Since $\hat{c}_p^{lG}(0.6, 0.2) = 1.479$, we conclude that the process

is capable, but we cannot draw the same conclusion if we ignore the measurement errors.

7 Conclusion

In this work we have been concerned with the problem of gauge measurement errors when dealing with process capability indices for one-sided tolerances. Grau [6] introduces the $C_p^u(u, v)$ and $C_p^l(u, v)$ indices to cover the processes with one-sided tolerances. The quality of a process is defined by the centring process and the proportion of non-conforming manufactured items. Grau [7] gives the elements that will allow the user to choose the pair (u, v) that will meet his needs as best as possible. In this paper we show that gauge measurement errors have a significant impact on the estimation of a process capability. The estimator evaluating the capability by using the sample data contaminated with gauge measurement errors severely underestimates the α -risk, resulting in a smaller testing power. We suggest an adjusted critical value to improve the accuracy of the capability assessment. For practical purpose we give a Maple program helpful to the users for their factory applications. Finally a real example in a company producing polymer granulates is used to assess the interest of the approach.

Appendix A:

– We have

$$\xi^u = \max(\xi, -\xi/k), \quad \xi^l = \max(\xi/k, -\xi) \quad (\text{A.1})$$

$$\xi = \begin{cases} \xi^u & \text{if } \xi > 0 \\ -k\xi^u & \text{if } \xi < 0 \end{cases}, \quad \xi = \begin{cases} k\xi^l & \text{if } \xi > 0 \\ -\xi^l & \text{if } \xi < 0 \end{cases} \quad (\text{A.2})$$

$$\xi_G^u = \max(\xi_G, -\xi_G/k), \quad \xi_G^l = \max(\xi_G/k, -\xi_G) \quad (\text{A.3})$$

$$\xi_G = \begin{cases} \xi_G^u & \text{if } \xi_G > 0 \\ -k\xi_G^u & \text{if } \xi_G < 0 \end{cases}, \quad \xi_G = \begin{cases} k\xi_G^l & \text{if } \xi_G > 0 \\ -\xi_G^l & \text{if } \xi_G < 0 \end{cases} \quad (\text{A.4})$$

– Since $\xi = (\mu - T)/\sigma$ and $\xi_G = (\mu - T)/\sigma_G$, we have

$$\xi_G = \xi/\sqrt{1 + \tau^2} \quad (\text{A.5})$$

$$\xi = \xi_G\sqrt{1 + \tau^2} \quad (\text{A.6})$$

– From (A.1) and (A.6), we have

$$\begin{aligned} \xi^u &= \max\left(\xi_G\sqrt{1 + \tau^2}, -\xi_G\sqrt{1 + \tau^2}/k\right), \\ \xi^l &= \max\left(\xi_G\sqrt{1 + \tau^2}/k, -\xi_G\sqrt{1 + \tau^2}\right) \end{aligned} \quad (\text{A.7})$$

– From (A.3), (A.5) and (A.1), we have

$$\xi_G^u = \xi^u/\sqrt{1 + \tau^2}, \quad \xi_G^l = \xi^l/\sqrt{1 + \tau^2} \quad (\text{A.8})$$

– Since $\xi^u = A_u^*/\sigma$ and $\xi^l = A_l^*/\sigma$, from (1) we have

$$\xi^u = \frac{-C_p^u u/3 + \sqrt{(C_p^u)^2 (u/3)^2 + ((C_p^u)^2 - (C_p^u(u, v))^2) (v (C_p^u(u, v))^2 - (u/3)^2)}}{v (C_p^u(u, v))^2 - (u/3)^2},$$

$$\xi^l = \frac{-C_p^l u/3 + \sqrt{(C_p^l)^2 (u/3)^2 + ((C_p^l)^2 - (C_p^l(u, v))^2) (v (C_p^l(u, v))^2 - (u/3)^2)}}{v (C_p^l(u, v))^2 - (u/3)^2} \quad (\text{A.14})$$

$$C_p^u = \sqrt{1 + v\xi^u} C_p^u(u, v) + u\xi^u/3,$$

$$C_p^l = \sqrt{1 + v\xi^l} C_p^l(u, v) + u\xi^l/3 \quad (\text{A.9})$$

– In the same manner, from (2) we have

$$C_p^{uG} = \sqrt{1 + v\xi_G^u} C_p^{uG}(u, v) + u\xi_G^u/3,$$

$$C_p^{lG} = \sqrt{1 + v\xi_G^l} C_p^{lG}(u, v) + u\xi_G^l/3 \quad (\text{A.10})$$

– From (A.10) and (3) we have

$$C_p^{uG} = \frac{\sqrt{1 + v\xi_G^u} \sqrt{1 + v\xi^u}}{\sqrt{1 + \tau^2 + v\xi^u}} C_p^u(u, v) + u\xi_G^u/3,$$

$$C_p^{lG} = \frac{\sqrt{1 + v\xi_G^l} \sqrt{1 + v\xi^l}}{3\sqrt{1 + \tau^2 + v\xi^l}} C_p^l(u, v) + u\xi_G^l/3 \quad (\text{A.11})$$

– Since $C_p^{uG} = C_p^{uG}(0, 0)$ and $C_p^u = C_p^u(0, 0)$, from (3)

$$C_p^{uG} = C_p^u / \sqrt{1 + \tau^2},$$

$$C_p^{lG} = C_p^l / \sqrt{1 + \tau^2} \quad (\text{A.12})$$

– From (A.12) and (A.11), we have

$$C_p^u = \sqrt{1 + \tau^2} \left(\frac{\sqrt{1 + v\xi_G^u} \sqrt{1 + v\xi^u}}{\sqrt{1 + \tau^2 + v\xi^u}} C_p^u(u, v) + u\xi_G^u/3 \right),$$

$$C_p^l = \sqrt{1 + \tau^2} \left(\frac{\sqrt{1 + v\xi_G^l} \sqrt{1 + v\xi^l}}{\sqrt{1 + \tau^2 + v\xi^l}} C_p^l(u, v) + u\xi_G^l/3 \right) \quad (\text{A.13})$$

– From (1), by a proof identical to Grau [15], we obtain
see equation (A.14) above

Appendix B:

The Maple Program to compute the critical value c_0^A

When the function H_G takes values that are too low, the Maple software is sometimes unable to perform the calculation of the integral of H_G . This is the reason why we limit the domain of integration $[0; K_G]$ to the domain $[K_0; K_1]$ on which $H_G > 10^{-8}$. This does not change the value of the integral for the required precision.

Algorithm

- Step 1. Read $u, v, k, \tau, n, \alpha, c, \hat{\xi}_G, B$ (the tolerance limit)
- Step 2. Compute $\hat{\xi}^u$ or $\hat{\xi}^l$ from (A.7), $\hat{\xi}_G^u$ or $\hat{\xi}_G^l$ from (A.3), C_p^u or C_p^l from (7) or (8), C_p^{uG} or C_p^{lG} from (A.12).
- Step 3. Compute H_G, K_G .
- Step 4. Find the adjusted critical value c_0^A from (6).
- Step 4.1. Find K_0 a lower integration bound.
- Step 4.2. Find K_1 an upper integration bound.
- Step 5. Print the adjusted critical value.
- Step 6. Plot the power test.
